

esm_dis_con, lag 1

Points: observed. 3% fall outside the 95% region (orange); about 5% should.

Phase plane: rate of change against the value it started from, shaded by the 50, 80 and 95% predictive regions. A linear model implies a band sloping down at the drift rate, the same everywhere. Observed points that curve, or that flatten at the extremes while the regions do not, indicate nonlinear dynamics. See `ctPhasePortrait()` for the model side of this on its own.
