

Mean PIT against the time interval since the previous observation, in equal−count bins; 0.5 is correct. A departure that depends on the interval implicates the dynamics −− drift or diffusion −− rather than the measurement model, which cannot know the interval. LogLik is each row's log−likelihood, and its distribution should match like any other quantity −− but the observed side is evaluated at the point estimate, so it carries no parameter uncertainty while the generated side does.
